

Case Study 1: Conversion Rates by Price Tier

This study analyzes the impact of product pricing on user behavior across different stages of the purchase funnel. Products are classified into Low, Medium, and High price tiers. For each tier, two key metrics are computed:

- View-to-Cart Conversion Rate
- Cart-to-Purchase Conversion Rate

The goal is to identify whether specific price segments exhibit significant drop-off rates. Insights from this analysis can inform pricing strategies and promotional targeting for underperforming product tiers.

Case Study 2: Session Duration and Purchase Likelihood

This study explores whether session length correlates with purchase probability. Sessions are categorized into Short, Medium, and Long based on the time elapsed between the first and last interaction. For each group, the percentage of sessions resulting in a purchase is measured.

These insights can help platforms detect high-intent users in real time, enabling timely interventions such as personalized recommendations or dynamic offers to boost conversion rates.

Case Study 3: Trampoline Product Identification

This study identifies trampoline products—items frequently viewed or added to carts in sessions that end in a purchase, yet are not purchased themselves. These products may act as intermediaries that influence buying decisions.

By recognizing such items, platforms can enhance recommendation engines by surfacing products that facilitate purchases indirectly through behavioral influence.

Case Study 4: Early Detection of User Churn

This study focuses on identifying early signals of user churn through week-over-week activity trends. By aggregating interaction counts per user across multiple weeks, patterns of declining engagement can be detected.

Early detection of churn risk enables proactive retention strategies, such as targeted incentives, push notifications, or re-engagement campaigns, to preserve long-term customer value.
